Preparation

Read in data and tidy up dataset

Plotting defaults

Descriptive data

The database contains data from 32 papers consisting of data from 2010 infants. In the tables below, we provide more descriptive information.

The next table shows what type of publications were included in our meta-analysis

publication_status	n_unique	count
dissertation	2	17
gray paper	2	14
paper	27	216
proceedings	1	4

Type of data on which we calculated effect sizes

The table below shows based on which data we calculated effect sizes.

es_method	n_unique	count
group_means_one	18	120
group_means_two	7	57
t_one	4	39
t_two	5	35

Type of comparison of the time-course data calculated

We also have different ways of comparison of the time-course data, as the next table shows.

within_measure_descriptive	n_unique	count
post-naming compared to pre-naming phase	10	29
post-naming phase compared with chance $(=50\%)$	9	23
post-pre difference score compared with chance $(=0)$	13	52

Type of distractor

This is a summary of the type of distractor used in an experiment

object_pair	count
familiar_familiar	23
$familiar_novel$	10

Whether word was pronounced both correctly as well as mispronounced

This is a summary of whether an experiment had both correct and mispronounced versions of the word in the experiment

word_correct_and_MP	count
	2
no	10
yes	21

Size of analysis time window

Where possible, we noted the time window for analysis. First, let's look at the offset (in milliseconds) after the start of the word, i.e. the begin of a give analysis window for a naming effect

```
offset_info <- time_wind_dat %>% group_by(offset) %>% summarize(count = n())
kable(offset_info)
```

offset	count
0	3
200	1
231	1
267	1
300	1
360	5
365	1
367	14
400	1
500	1
1133	1
NA	4

Duration of post naming window

Next we look at duration (in seconds) of the post naming window, here, too, we see a lot of heterogeneity.

duration_info <- db_ET_correct %>% group_by(post_nam_dur) %>% summarize(count = n())

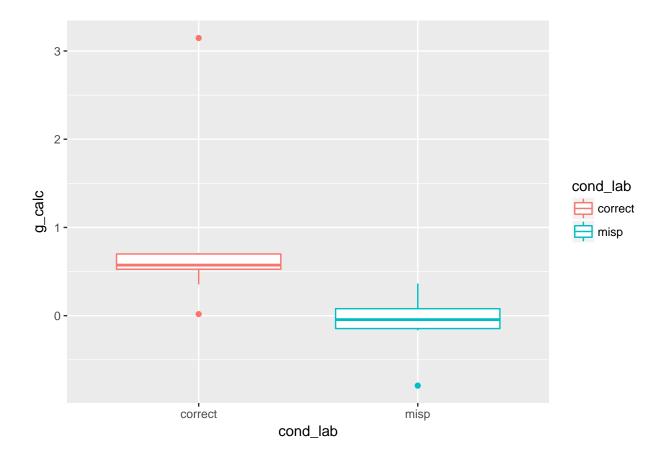

kable(duration_info)

$post_{-}$	_namdur	count
	1.510	2
	2.000	45
	2.500	18
	2.600	4
	2.750	4
	2.767	1
	2.805	4
	3.000	13
	3.500	6
	4.000	6
	6.000	1

In summary, we see little consistency in analysis methods of comparable studies looking at naming and mispronunciation effects.

Mispronunciation Sensitivity in the youngest ages

Even the youngest ages in the database (less than 1 year) show mispronunciation sensitivity

Plot Mispronunciation Effect by Age (bw)

Correlation MP effect and Vocabulary

First, let's take a look at which vocabulary data we have available.

```
vocab_info <- db_ET_correct %>% mutate(has_vocab = ifelse(!is.na(r_comprehension),
    "comprehension", ifelse(!is.na(r_production), "production", "none"))) %>%
    group_by(has_vocab) %>% summarize(count = n())
kable(vocab_info)
```

has_vocab	count
comprehension	12
none	87
production	5

We have 17 correlations, roughly evenly divided between comprehension and production data. There is reason to believe that production data are different from comprehension data (the former being easier to estimate for parents in the typical questionnaire-based assessment), so we should both analyze this data separately and see whether it makes sense in a joint analysis.

```
# we're relying on the library meta function metacor
compr <- subset(db_ET_correct, !is.na(db_ET_correct$r_comprehension) & r_comprehension >
    -1)
metacor(cor = r_comprehension, n = n_1, studlab = short_cite, data = compr,
    sm = "COR")
